Rev Up Feature updates Inventory updates Surveillance updates Nyctimene Updates Moves into action button etc Software validation Manual installation etc Run SQL queries for network, hardware etc and database schema versions Bump software release numbers Make any other changes required by software Uninstall / remove / add server with correct versions etc Create test database, set up new server Backup / restore data Create Test server from backup Create reports from test server Prepare change data for testing Test data integration, integration tests, automated testing, manual testing, load testing etc Make final preparations for new server Stop old server Deploy final changes Start new server Upgrade test database to final model Production is one step ahead of testing Change database names / drop and create tables Rebuild indexes Update data Install new application / change versions etc Test application with load tests, high traffic testing, performance testing, automated testing Test application with user testing, process testing etc Final testing Start production server, ready for new release Submit new release The real life scenario is that the scenario starts when the first new client installs the product. What has been suggested so far The first phase of the software deployment is to set up the database and content of the tables. What would be the best practice to do this? Create the tables and content and then upgrade to the new software version in one step? How do you manage the databases / the content of the tables? Can you use DB integration tools like SQL manager? Are there other tools out there for this purpose? A: SQL Server Management Studio, Database Project is a tool to use. It's also something that is built-in to TFS and other SCM's. I don't know your environment so I'll stick to 82157476af
